Lecturer: Lucian Buşoniu

# Part IV

## Correlation analysis

# Motivation 1

## Why other techniques than transient analysis?

Transient analysis of step and impulse responses:

- Only works for a few system orders
- Must usually be done (semi-)manually
- Gives a rough, heuristic model of the system

The upcoming system identification methods:

- Work for arbitrary system orders
- Provide fully implementable, automatic algorithms
- Have solution accuracy guarantees (under appropriate conditions)

# Motivation 2

## Why correlation analysis?

- Closest to transient analysis (model = impulse response)
- True nonparametric model
- “Simple” general identification technique

# Classification

Recall **taxonomy of models** from Part I:

By number of parameters:

- 1 Parametric models: have a fixed form (mathematical formula), with a known, often small number of parameters
- 2 **Nonparametric models**: cannot be described by a fixed, small number of parameters  
Often represented as graphs or tables

By amount of prior knowledge (“color”):

- 1 First-principles, white-box models: fully known in advance
- 2 **Black-box models**: entirely unknown
- 3 Gray-box models: partially known

Correlation analysis is truly a nonparametric method; it produces an *impulse response model*.

# Table of contents

- 1 Ideal correlation analysis method
- 2 A practical algorithm. FIR model
- 3 Matlab example
- 4 Accuracy guarantee (simplified)

# Recall: discrete-time model

# Discrete-time impulse response

Discrete-time, unit impulse signal:

$$u_I(k) = \begin{cases} 1 & k = 0 \\ 0 & k > 0 \end{cases}$$

(does not have area 1, so it's different from the discrete-time realization of the continuous-time impulse!)

Discrete-time impulse response:

$$y_I(k) = h(k), \quad k \geq 0$$

$h(k), k \geq 0$  is also called the **weighting function** of the system.

# Impulse response model: Problem

Take a discrete-time input  $u(k)$ . Our objective is to find the resulting output  $y(k)$ .

# Impulse response model: Input decomposition

Consider a signal  $\tilde{u}_j(k)$  equal to  $u(j)$  at  $k = j$ , and 0 elsewhere; just a shifted and scaled unit impulse:

$$\tilde{u}_j(k) = u(j)u_1(k - j)$$

So, the response to  $\tilde{u}_j(k)$  is a shifted and scaled impulse response:

$$\tilde{y}_j(k) = u(j)h(k - j)$$

# Impulse response model: Superposition

Now,  $u(k)$  is the superposition of all signals  $\tilde{u}_j$ , so due to linearity:

$$y(k) = \sum_{j=0}^k \tilde{y}_j(k) = \sum_{j=0}^k u(j)h(k-j)$$

# Impulse response model: Convolution

$$y(k) = \sum_{j=0}^k \tilde{y}_j(k) = \sum_{j=0}^k u(j)h(k-j) = \sum_{j=0}^k h(j)u(k-j) = \sum_{j=0}^{\infty} h(j)u(k-j)$$

where zero initial conditions were assumed, i.e.  $u(j) = 0 \forall j < 0$ .

# Impulse-response model

The response to an arbitrary signal  $u(k)$  is the *convolution* of the input and the impulse response:

$$y(k) = \sum_{j=0}^{\infty} h(j)u(k-j) + v(k)$$

where we included an additional disturbance term  $v(k)$ .

# Assumptions

## Assumptions

- 1 The input  $u(k)$  is a stationary stochastic process.
- 2 The input  $u(k)$  and the disturbance  $v(k)$  are independent.

### Recall:

- Independence of random variables.
- Stationary stochastic process: constant mean at every time step, covariance only depends on difference between time steps and not on absolute time.

# Covariance function between input and output

$$r_{yu}(\tau) = E \{y(k + \tau)u(k)\} \left( = \frac{1}{\#} \sum_k y(k + \tau)u(k) \right)$$

For instance:

$$r_{yu}(2) = E \{y(k + 2)u(k)\} = \frac{1}{\#} \sum_k y(k + 2)u(k)$$

$$r_{yu}(3) = E \{y(k + 3)u(k)\}$$

$$r_{yu}(-1) = E \{y(k - 1)u(k)\} = E \{y(k)u(k + 1)\}$$

# Covariance function of the input

$$r_u(\tau) = r_u(-\tau) = E \{u(k + \tau)u(k)\} \left( = \frac{1}{\#} \sum_k u(k + \tau)u(k) \right)$$

For instance:

$$r_u(2) = r_u(-2) = E \{u(k + 2)u(k)\}$$

$$r_u(3) = r_u(-3) = E \{u(k + 3)u(k)\}$$

**Notes:**  $r_u$  is symmetrical, and  $r_{yu}$ ,  $r_u$  are true covariances only when the input and output are zero-mean, so if they are not, then the means must be subtracted prior to applying the method.

# Relationship of covariances and impulse response

If there were no disturbance, then:

$$\begin{aligned}
 r_{yu}(\tau) &= E \{y(k + \tau)u(k)\} \\
 &= E \left\{ \left[ \sum_{j=0}^{\infty} h(j)u(k + \tau - j) \right] u(k) \right\} \\
 &= \sum_{j=0}^{\infty} h(j)E \{u(k + \tau - j)u(k)\} = \sum_{j=0}^{\infty} h(j)r_u(\tau - j)
 \end{aligned}$$

The errors coming from the disturbance are dealt with later, implicitly, using linear regression.

# Impulse response identification

Writing the covariance relationship for all  $\tau$ :

$$r_{yu}(0) = \sum_{j=0}^{\infty} h(j)r_u(-j) = h(0)r_u(0) + h(1)r_u(-1) + h(2)r_u(-2) + \dots$$

$$r_{yu}(1) = \sum_{j=0}^{\infty} h(j)r_u(1-j) = h(0)r_u(1) + h(1)r_u(0) + h(2)r_u(-1) + \dots$$

...

we obtain (in principle) an infinite system of linear equations:

- Coefficients  $r_u(\tau)$ ,  $r_{yu}(\tau)$ .
- Unknowns  $h(0)$ ,  $h(1)$ ,  $\dots$ : solution of the system.

# Linear system structure

$$r_{yu}(\tau) = \sum_{j=0}^{\infty} h(j)r_u(-j) = h(0)r_u(\tau) + h(1)r_u(\tau - 1) + h(2)r_u(\tau - 2) + \dots$$

$r_{yu}(0)$	=	<table style="border-collapse: collapse; text-align: center;"> <tr> <td style="border: 1px solid blue; padding: 5px;"><math>r_u(0)</math></td> <td style="border: 1px solid red; padding: 5px;"><math>r_u(1)</math></td> <td style="border: 1px solid green; padding: 5px;"><math>r_u(2)</math></td> <td style="border: 1px solid purple; padding: 5px;"><math>r_u(3)</math></td> <td style="padding: 5px;">...</td> <td style="padding: 5px;"></td> <td style="padding: 5px;"></td> <td style="padding: 5px;"></td> </tr> <tr> <td style="border: 1px solid red; padding: 5px;"><math>r_u(1)</math></td> <td style="border: 1px solid blue; padding: 5px;"><math>r_u(0)</math></td> <td style="border: 1px solid green; padding: 5px;"><math>r_u(1)</math></td> <td style="border: 1px solid purple; padding: 5px;"><math>r_u(2)</math></td> <td style="border: 1px solid black; padding: 5px;"><math>r_u(3)</math></td> <td style="padding: 5px;">...</td> <td style="padding: 5px;"></td> <td style="padding: 5px;"></td> </tr> <tr> <td style="border: 1px solid green; padding: 5px;"><math>r_u(2)</math></td> <td style="border: 1px solid red; padding: 5px;"><math>r_u(1)</math></td> <td style="border: 1px solid blue; padding: 5px;"><math>r_u(0)</math></td> <td style="border: 1px solid purple; padding: 5px;"><math>r_u(1)</math></td> <td style="border: 1px solid green; padding: 5px;"><math>r_u(2)</math></td> <td style="border: 1px solid black; padding: 5px;"><math>r_u(3)</math></td> <td style="padding: 5px;">...</td> <td style="padding: 5px;"></td> </tr> <tr> <td style="border: 1px solid purple; padding: 5px;"><math>r_u(3)</math></td> <td style="border: 1px solid green; padding: 5px;"><math>r_u(2)</math></td> <td style="border: 1px solid red; padding: 5px;"><math>r_u(1)</math></td> <td style="border: 1px solid blue; padding: 5px;"><math>r_u(0)</math></td> <td style="border: 1px solid red; padding: 5px;"><math>r_u(1)</math></td> <td style="border: 1px solid green; padding: 5px;"><math>r_u(2)</math></td> <td style="border: 1px solid purple; padding: 5px;"><math>r_u(3)</math></td> <td style="padding: 5px;">...</td> </tr> <tr> <td style="padding: 5px;">⋮</td> <td style="padding: 5px;">⋮</td> <td style="padding: 5px;"></td> <td style="padding: 5px;"></td> <td style="padding: 5px;"></td> <td style="padding: 5px;"></td> <td style="padding: 5px;"></td> <td style="padding: 5px;"></td> </tr> </table>	$r_u(0)$	$r_u(1)$	$r_u(2)$	$r_u(3)$	...				$r_u(1)$	$r_u(0)$	$r_u(1)$	$r_u(2)$	$r_u(3)$	...			$r_u(2)$	$r_u(1)$	$r_u(0)$	$r_u(1)$	$r_u(2)$	$r_u(3)$	...		$r_u(3)$	$r_u(2)$	$r_u(1)$	$r_u(0)$	$r_u(1)$	$r_u(2)$	$r_u(3)$	...	⋮	⋮							•	<table style="border-collapse: collapse; text-align: center;"> <tr> <td style="padding: 5px;"><math>h(0)</math></td> </tr> <tr> <td style="padding: 5px;"><math>h(1)</math></td> </tr> <tr> <td style="padding: 5px;"><math>h(2)</math></td> </tr> <tr> <td style="padding: 5px;"><math>h(3)</math></td> </tr> <tr> <td style="padding: 5px;">⋮</td> </tr> </table>	$h(0)$	$h(1)$	$h(2)$	$h(3)$	⋮

Next, a practical algorithm working with finite data is given.

# Table of contents

- 1 Ideal correlation analysis method
- 2 A practical algorithm. FIR model**
- 3 Matlab example
- 4 Accuracy guarantee (simplified)

# Finite impulse response model

Impose the condition  $h(k) = 0$  for  $k \geq M$ . We obtain the **finite impulse response (FIR)** model:

$$y(k) = \sum_{j=0}^{M-1} h(j)u(k-j) + v(k)$$

**Note:**  $M$  must be taken so that  $MT_s \gg$  dominant time constants (or equivalently, the system is close to steady-state)

# Covariances from data: $r_u$

Consider we are given signals  $u(k), y(k)$  with  $k = 0, \dots, N$ .  
We have, for positive  $\tau$ :

$$r_u(\tau) = E \{u(k + \tau)u(k)\}$$

$$\approx \frac{1}{N} \sum_{k=0}^{N-\tau} u(k + \tau)u(k)$$

$$=: \hat{r}_u(\tau), \quad \forall \tau \geq 0$$

and  $\hat{r}_u(-\tau) = \hat{r}_u(\tau)$  due to symmetry.

# Covariances from data: $r_{yu}$

For positive and negative  $\tau$ :

$$r_{yu}(\tau) = E \{y(k + \tau)u(k)\}$$

$$\approx \begin{cases} \frac{1}{N} \sum_{k=0}^{N-\tau} y(k + \tau)u(k) & \text{if } \tau \geq 0 \\ \frac{1}{N} \sum_{k=-\tau}^N y(k + \tau)u(k) & \text{if } \tau < 0 \end{cases}$$

$$=: \hat{r}_{yu}(\tau), \quad \forall \tau \geq 0$$

# Finite covariance relationship

FIR equation:

$$y(k) = \sum_{j=0}^{M-1} h(j)u(k-j) + v(k)$$

The covariance relationship is similarly truncated:

$$r_{yu}(\tau) = \sum_{j=0}^{M-1} h(j)r_u(\tau-j)$$

# Linear system

Using  $\hat{r}_{yu}$ ,  $\hat{r}_u$  estimated from data, write the truncated equations for  $\tau = 0, \dots, T - 1$  (keeping in mind that  $\hat{r}_u(-\tau) = \hat{r}_u(\tau)$ ):

$$\hat{r}_{yu}(0) = \sum_{j=0}^{M-1} h(j)\hat{r}_u(-j)$$

$$= h(0)\hat{r}_u(0) + h(1)\hat{r}_u(1) + \dots + h(M-1)\hat{r}_u(M-1)$$

$$\hat{r}_{yu}(1) = \sum_{j=0}^{M-1} h(j)\hat{r}_u(1-j)$$

$$= h(0)\hat{r}_u(1) + h(1)\hat{r}_u(0) + \dots + h(M-1)\hat{r}_u(M-2)$$

...

$$\hat{r}_{yu}(T-1) = \sum_{j=0}^{M-1} h(j)\hat{r}_u(T-1-j)$$

$$= h(0)\hat{r}_u(T-1) + h(1)\hat{r}_u(T-2) + \dots + h(M-1)\hat{r}_u(T-M)$$

– a linear system of  $T$  equations in  $M$  unknowns  $h(0), \dots, h(M-1)$ .

# Linear system: Matrix form

$$\begin{bmatrix} \hat{r}_{yu}(0) \\ \hat{r}_{yu}(1) \\ \vdots \\ \hat{r}_{yu}(T-1) \end{bmatrix} = \begin{bmatrix} \hat{r}_u(0) & \hat{r}_u(1) & \dots & \hat{r}_u(M-1) \\ \hat{r}_u(1) & \hat{r}_u(0) & \dots & \hat{r}_u(M-2) \\ \vdots & \vdots & \ddots & \vdots \\ \hat{r}_u(T-1) & \hat{r}_u(T-2) & \dots & \hat{r}_u(T-M) \end{bmatrix} \cdot \begin{bmatrix} h(0) \\ h(1) \\ \vdots \\ h(M-1) \end{bmatrix}$$

# Linear system: Notes

Naively taking  $T = M$  would give an exact system solution, but due to noise and disturbances this solution would be overfitted. So it is necessary to take  $T > M$  (preferably,  $T \gg M$ ).

Then we can apply the machinery of linear regression (see Part 3) to solve this problem.

# Using the FIR model

Once the system has been solved for the estimated  $\hat{h}$ , we predict outputs with:

$$\hat{y}(k) = \sum_{j=0}^{M-1} \hat{h}(j)u(k-j)$$

## Special case: White noise input

Consider the case when the input  $u(k)$  is zero-mean white noise.

Then,  $r_u(\tau) = 0$  whenever  $\tau \neq 0$  (since white noise is uncorrelated), and  $r_{yu}(\tau) = \sum_{j=0}^{\infty} h(j)r_u(\tau - j)$  simplifies to:

$$r_{yu}(\tau) = h(\tau)r_u(0)$$

This leads to the easy algorithm:

$$\hat{h}(\tau) = \frac{\hat{r}_{yu}(\tau)}{\hat{r}_u(0)}$$

# Table of contents

- 1 Ideal correlation analysis method
- 2 A practical algorithm. FIR model
- 3 Matlab example**
- 4 Accuracy guarantee (simplified)

# Experimental data

Consider we are given the following, separate, identification and validation data sets.

```
plot(id); and plot(val);
```

There are 2500 samples in the identification data. We notice that the data is zero-mean.

# Input covariance

```
[c, tau] = xcorr(id.u); and plot(tau, c);
```

The input is white noise.

# Applying correlation analysis

```
fir = cra(id, M, 0); or fir = cra(id, M, 0, plotlevel);
```

Arguments:

- 1 Identification data.
- 2 FIR length  $M$ , here it is set to 50.
- 3 Third argument 0 means no *input whitening* is performed.

Dealing with non-ideal inputs:

- If input is not zero-mean, pass the data through `detrend` to remove the means.
- If input is not white noise, the third argument should be left to default (by not specifying it or setting it to an empty matrix), which means input whitening is performed.

# Applying correlation analysis (continued)

By default (or with `plotlevel=1`) the FIR parameters are shown with a 99% confidence interval.

`plotlevel=2` also produces the covariance functions.

# Results on the identification data

```
yhat = conv(fir, id.u); yhat = yhat(1:length(id.u));
```

To simulate the FIR model, a *convolution* between the FIR parameters and the input is performed. The simulated output is longer than needed so we cut it off at the right length.

# Validation of the FIR model

```
yhat = conv(fir, val.u); yhat = yhat(1:length(val.u));
```

Results OK, not great.

# Insight into the different signals

## Alternative: `impulseest` function

```
model = impulseest(id, M); or model = impulseest(id);
```

Uses a more involved algorithm than the one studied in the lectures.

# Table of contents

- 1 Ideal correlation analysis method
- 2 A practical algorithm. FIR model
- 3 Matlab example
- 4 Accuracy guarantee (simplified)**

# Simplified guarantee in the white-noise case

## Additional assumption

- 1 The input  $u(k)$  is zero-mean white noise.

## Theorem

In the white-noise case, as the number of data points  $N$  grows to infinity, the estimates  $\hat{h}(\tau)$  converge to the true values  $h(\tau)$ .

**Remark:** This type of property, where the true solution is obtained in the limit of infinite data, is called *consistency*.

# Summary

- Discrete-time unit impulse and impulse response  $h$ .
- Using impulse response as a model: convolution with input  $u$ .
- Ideal covariance functions and linear system of equations in  $h$ .
- Practical correlation analysis:
  - covariance from finite data
  - finite impulse response (FIR) model
  - finite-dimensional linear system
- Matlab example.
- Simplified accuracy guarantee (consistency for infinite data).
