Recall taxonomy of models from Part I:

By number of parameters:

- Parametric models: have a fixed form (mathematical formula), with a known, often small number of parameters
- Nonparametric models: cannot be described by a fixed, small number of parameters Often represented as graphs or tables

By amount of prior knowledge ("color"):

- First-principles, white-box models: fully known in advance
- Black-box models: entirely unknown
- Gray-box models: partially known

Like prediction error methods, instrumental variable methods produce *black-box*, *parametric*, polynomial models.

- The ARX method is simple (linear regression), but only supports limited classes of disturbance
- General PEM supports any (reasonable) disturbance, but it is relatively difficult to apply from a numerical point of view

Can we come up with a method that combines both advantages?

(qualified) Yes! Instrumental variables

Analytical development of IV methods

Matlab example

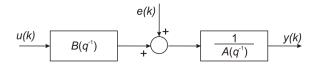

Theoretical guarantees

Closed-loop identification using IV

Recall: ARX model

$$A(q^{-1})y(k) = B(q^{-1})u(k) + e(k)$$

(1+a₁q⁻¹ + ... + a_{na}q^{-na})y(k) =
(b₁q⁻¹ + ... + b_{nb}q^{-nb})u(k) + e(k)

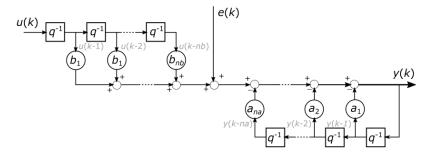

In explicit form:

$$y(k) = -a_1y(k-1) - a_2y(k-2) - \dots - a_{na}y(k-na)$$

$$b_1u(k-1) + b_2u(k-2) + \dots + b_{nb}u(k-nb) + e(k)$$

where the model parameters are: $a_1, a_2, \ldots, a_{n_a}$ and b_1, b_2, \ldots, b_{nb} .

Recall: Linear regression representation

$$y(k) = \begin{bmatrix} -y(k-1) & \cdots & -y(k-na) & u(k-1) & \cdots & u(k-nb) \end{bmatrix}$$
$$\cdot \begin{bmatrix} a_1 & \cdots & a_{na} & b_1 & \cdots & b_{nb} \end{bmatrix}^\top + e(k)$$
$$=: \varphi^\top(k)\theta + e(k)$$

Regressor vector: $\varphi \in \mathbb{R}^{na+nb}$, previous output and input values. Parameter vector: $\theta \in \mathbb{R}^{na+nb}$, polynomial coefficients.

Given dataset u(k), y(k), k = 1, ..., N, find model parameters θ to achieve small errors $\varepsilon(k)$ in:

$$\mathbf{y}(\mathbf{k}) = \varphi^{\top}(\mathbf{k})\theta + \varepsilon(\mathbf{k})$$

Formal objective: minimize the mean squared error:

$$V(heta) = rac{1}{N}\sum_{k=1}^Narepsilon(k)^2$$

Solution: can be written in several ways, here we use:

$$\widehat{\theta} = \left[\frac{1}{N}\sum_{k=1}^{N}\varphi(k)\varphi^{\top}(k)\right]^{-1}\left[\frac{1}{N}\sum_{k=1}^{N}\varphi(k)y(k)\right]$$

Parameter errors

 $\widehat{\theta}$

Finally, recall that for the guarantees, a true parameter vector θ_0 is assumed to exist:

$$\mathbf{y}(\mathbf{k}) = \varphi^{ op}(\mathbf{k})\theta_0 + \mathbf{v}(\mathbf{k})$$

Analyze the parameter errors (a vector of *n* elements):

$$\begin{split} \hat{T} - \theta_0 &= \left[\frac{1}{N}\sum_{k=1}^N \varphi(k)\varphi^{\mathsf{T}}(k)\right]^{-1} \left[\frac{1}{N}\sum_{k=1}^N \varphi(k)\mathbf{y}(k)\right] \\ &- \left[\frac{1}{N}\sum_{k=1}^N \varphi(k)\varphi^{\mathsf{T}}(k)\right]^{-1} \left[\frac{1}{N}\sum_{k=1}^N \varphi(k)\varphi^{\mathsf{T}}(k)\right] \theta_0 \\ &= \left[\frac{1}{N}\sum_{k=1}^N \varphi(k)\varphi^{\mathsf{T}}(k)\right]^{-1} \left[\frac{1}{N}\sum_{k=1}^N \varphi(k)[\mathbf{y}(k) - \varphi^{\mathsf{T}}(k)\theta_0]\right] \\ &= \left[\frac{1}{N}\sum_{k=1}^N \varphi(k)\varphi^{\mathsf{T}}(k)\right]^{-1} \left[\frac{1}{N}\sum_{k=1}^N \varphi(k)\mathbf{y}(k)\right] \end{split}$$

We wish the algorithm to be consistent: the parameter errors should become 0 in the limit of infinite data (and they should be well-defined).

As
$$N \to \infty$$
:

$$\frac{1}{N} \sum_{k=1}^{N} \varphi(k) \varphi^{\top}(k) \to \mathrm{E} \left\{ \varphi(k) \varphi^{\top}(k) \right\}$$

$$\frac{1}{N} \sum_{k=1}^{N} \varphi(k) v(k) \to \mathrm{E} \left\{ \varphi(k) v(k) \right\}$$

For the error to be (1) well-defined and (2) equal to zero, we need:

- E { $\varphi(k)\varphi^{\top}(k)$ } invertible.
- 2 $E \{\varphi(k)v(k)\}$ zero.

Analytical development of IV methods Matlab example Theoretical guarantees OOOOOOOOOOOOOOOOOOOOOOOOOOOOOOOOOOOO	Closed-loop identification using IV

vvnite noise required

- We have E {φ(k)v(k)} = 0 if the elements of φ(k) are uncorrelated with v(k) (note that v(k) is assumed zero-mean).
- But $\varphi(k)$ includes $y(k-1), y(k-2), \ldots$, which depend on $v(k-1), v(k-2), \ldots$!
- So the only option is to have v(k) uncorrelated with $v(k-1), v(k-2), \ldots \Rightarrow v(k)$ must be *white noise*.

Instrumental variables are a solution to remove this limitation to white noise.

Intuition			

πιωιιν

$$\widehat{\theta} - \theta_0 = \left[\frac{1}{N}\sum_{k=1}^N \varphi(k)\varphi^\top(k)\right]^{-1} \left[\frac{1}{N}\sum_{k=1}^N \varphi(k)v(k)\right]$$

Idea: What if a different vector than $\varphi(k)$ could be included in the product with v(k)?

$$\widehat{\theta} - \theta_0 = \left[\frac{1}{N}\sum_{k=1}^N Z(k)\varphi^\top(k)\right]^{-1} \left[\frac{1}{N}\sum_{k=1}^N Z(k)\nu(k)\right]$$

where the elements of Z(k) are uncorrelated with v(k). Then E {Z(k)v(k)} = 0 and the error can be zero.

Vector Z(k) has *n* elements, which are called instruments.

Analytical development of IV methods

Matlab example

Theoretical guarantees

Closed-loop identification using IV

Instrumental variable method

In order to have:

$$\widehat{\theta} - \theta_0 = \left[\frac{1}{N}\sum_{k=1}^N Z(k)\varphi^{\top}(k)\right]^{-1} \left[\frac{1}{N}\sum_{k=1}^N Z(k)v(k)\right]$$
(8.1)

the estimated parameter must be:

$$\widehat{\theta} = \left[\frac{1}{N}\sum_{k=1}^{N} Z(k)\varphi^{\top}(k)\right]^{-1} \left[\frac{1}{N}\sum_{k=1}^{N} Z(k)y(k)\right]$$
(8.2)

This $\hat{\theta}$ is the solution to the system of *n* equations:

$$\left[\frac{1}{N}\sum_{k=1}^{N}Z(k)[\varphi^{\top}(k)\theta-y(k)]\right]=0$$
(8.3)

Constructing and solving this system gives the basic instrumental variable (IV) method.

Exercise: Show that (8.3) implies (8.2), and that (8.2) implies (8.1).

Simple instrument	te		
Analytical development of IV methods	Matlab example	Theoretical guarantees	Closed-loop identification using IV

So far the instruments Z(k) were not discussed. They are usually created based on the inputs (including outputs would lead to correlation with v and so eliminate the advantage of IV).

Simple possibility: just include additional delayed inputs to obtain a vector of the appropriate size, n = na + nb:

 $Z(k) = [u(k - nb - 1), \dots u(k - na - nb), u(k - 1), \dots, u(k - nb)]^{\top}$

Compare to original vector:

 $\varphi(k) = \left[-y(k-1), \ldots, -y(k-na), u(k-1), \ldots, u(k-nb)\right]^{\top}$

Question: Why not just include $u(k - 1), \ldots, u(k - na)$?

Analytical development of IV methods	Matlab example	Theoretical guarantees	Closed-loop identification using IV
Generalization			

Take *na* past values from generic instrumental variable *x*:

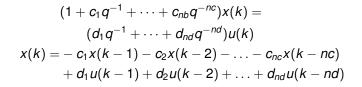

$$Z(k) = [-x(k-1), \dots, -x(k-na), u(k-1), \dots, u(k-nb)]^{\top}$$

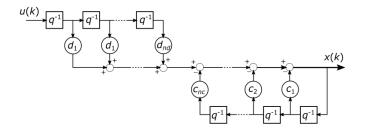

which is the output of a transfer function with *u* at the input:

$$C(q^{-1})x(k) = D(q^{-1})u(k)$$

Remark: $C(q^{-1})$, $D(q^{-1})$ have different meanings than in PEM.

Analytical development of IV methods Mattab example Closed-loop identification using Cococo Coco Cococo Cococo Cococo Cococo Cococo Coco Cococo Cococo Cococo Cococo Cococo Cococo Coco Coco

In order to obtain:

$$Z(k) = [u(k - nb - 1), \dots u(k - na - nb), u(k - 1), \dots, u(k - nb)]^{\top}$$

set C = 1, $D = -q^{-nb}$.

Exercise: Verify that the desired Z(k) is indeed obtained.

Matlab example

Theoretical guarantees

Closed-loop identification using IV

Generalized instruments: Initial model

Generalized instruments:

 $Z(k) = [-x(k-1), \dots, -x(k-na), u(k-1), u(k-2), \dots, u(k-nb)]^{\top}$

Compare to original vector:

 $\varphi(k) = \left[-y(k-1), \ldots, -y(k-na), u(k-1), \ldots, u(k-nb)\right]^{\top}$

Idea: Take instrument generator equal to an initial model, $C(q^{-1}) = \widehat{A}(q^{-1}), D(q^{-1}) = \widehat{B}(q^{-1})$. This model can be obtained e.g. with ARX estimation.

The instruments are an approximation of *y*:

 $Z(k) = [-\hat{y}(k-1), \dots - \hat{y}(k-na), u(k-1), \dots, u(k-nb)]^{\top}$ that has the crucial advantage of being *uncorrelated* with the noise.

Table of contents

1

Analytical development of instrumental variable methods

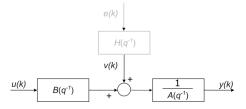

- Starting point: ARX
- Instrumental variables methods
- Comparison: IV versus PEM
- 2 Matlab example
- 3 Theoretical guarantees
- 4 Closed-loop identification using IV

Comparison

Both PEM and IV can be seen as extensions of ARX:

$$A(q^{-1})y(k) = B(q^{-1})u(k) + e(k)$$

to disturbances v(k) different from white noise e(k).

- PEM explicitly include the disturbance model in the structure, e.g. in ARMAX $v(k) = C(q^{-1})e(k)$ leading to $A(q^{-1})y(k) = B(q^{-1})u(k) + C(q^{-1})e(k).$
- IV methods do *not* explicitly model the disturbance, but are designed to be resilient to non-white, "colored" disturbance, by using instruments *Z*(*k*) uncorrelated with it.

Matlab example

Theoretical guarantees

Closed-loop identification using IV

Comparison (continued)

Advantage of IV: Simple model structure, identification consists only of solving a system of linear equations. In contrast, PEM required solving optimization problems with e.g. Newton's method, was susceptible to local minima etc.

Disadvantage of IV (why it was only a *qualified* yes in the beginning): In practice, for finite number N of data, model quality depends heavily on the choice of instruments Z(k). Moreover, the resulting model has a larger risk of being unstable (even for a stable real system).

Methods exist to choose instruments Z(k) that are optimal in a certain sense, but they will not be discussed here.

Analytical development of IV methods	Matlab example	Theoretical guarantees	Closed-loop identification using IV

Table of contents

Analytical development of instrumental variable methods

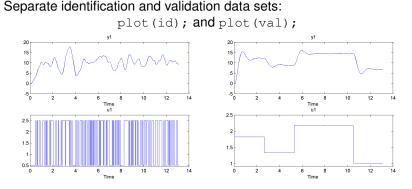

2 Matlab example

3 Theoretical guarantees

Analytical development of IV methods Matlab example Theoretical guarantees Closed-loop identification using IV 00000

Experimental data

From prior knowledge, the system has order 2 and the disturbance is colored (does not obey the ARX model structure).

Remarks: As before, the identification input is a pseudo-random binary signal, and the validation input a sequence of steps.

IV identification with custom instruments

```
Define the instruments by the generating transfer function, using polynomials C(q^{-1}) and D(q^{-1}).
model = iv(id, [na, nb, nk], C, D);
```

Arguments:

- Identification data.
- Array containing the orders of A and B and the delay nk (like for ARX).
- Polynomials C and D, as vectors of coefficients in increasing power of q⁻¹.

Analytical development of IV methods

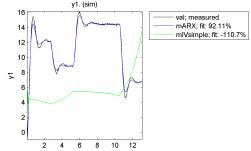

Matlab example

Theoretical guarantees

Closed-loop identification using IV

Result with simple instruments

Take $C(q^{-1}) = 1$, $D(q^{-1}) = -q^{-nb}$, leading to $Z(k) = [u(k - nb - 1), \dots, u(k - na - nb), u(k - 1), \dots, u(k - nb)]^{\top}$. Compare to ARX.

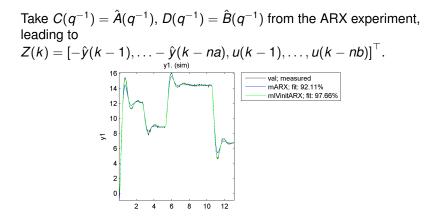

Conclusions:

- Model unstable ⇒ in general, must pay attention because IV models are not guaranteed to be stable! (recall the Comparison)
- Results very bad with this simple choice.

Analytical development of IV methods Mattab example 000000 Theoretical guarantees 000000 Closed-loop identification using IV 000000

Result with ARX-model instruments

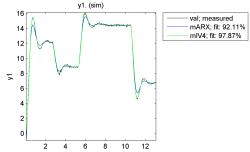

Conclusion: IV obtains better results. This is because the disturbance is colored, and IV can deal effectively with this case (whereas ARX cannot – but it still provides a useful starting point for IV).

model = iv4(id, [na, nb, nk]);

Implements an algorithm that generates near-optimal instruments.

Conclusion: Virtually the same performance as ARX instruments.

Analytical development of IV methods	Matlab example	Theoretical guarantees ●0000	Closed-loop identification using IV
- - - - - - -			

Table of contents

2 Matlab example

Theoretical guarantees

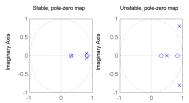

Assumptions			
Analytical development of IV methods	Matlab example	Theoretical guarantees	Closed-loop identification using IV

Assumptions (simplified)

- The disturbance $v(k) = H(q^{-1})e(k)$ where e(k) is zero-mean white noise, and $H(q^{-1})$ is a transfer function satisfying certain conditions.
- The input signal u(k) has a sufficiently large order of PE and does not depend on the disturbance (the experiment is open-loop).
- The real system is stable and *uniquely* representable by the model chosen: there exists exactly one θ_0 so that polynomials $A(q^{-1}; \theta_0)$ and $B(q^{-1}; \theta_0)$ are identical to those of the real system.
- Matrix E $\{Z(k)Z^{\top}(k)\}$ is invertible.

Discussion of assumptions

- Assumption 1 shows the main advantage of IV over PEM: the disturbance can be colored.
- Assumptions 2 and 3 are not very different from those made by PEM. Stability of a discrete-time system requires its poles to be strictly inside the unit circle:

Question: Why is the experiment not allowed to be closed-loop?

• Assumption 4 is required to solve the linear system, and given an input with sufficient order of PE boils down to an appropriate selection of instruments (e.g. not repeating the same delayed input u(k - i) twice).

Guarantee

Theorem 1

As the number of data points $N \to \infty$, the solution $\hat{\theta}$ of IV estimation converges to the true parameter vector θ_0 .

Remark: This is a consistency guarantee, in the limit of infinitely many data points.

Analytical development of IV methods	

Possible extensions

- Multiple-input, multiple-output systems.
- Larger-dimension instruments Z than parameter vectors θ with other modifications, called extended IV methods.
- Identification of systems operating in closed loop: next

Table of contents

Analytical development of instrumental variable methods

2 Matlab example

3 Theoretical guarantees

Closed-loop identification using IV

Motivation

In practice, systems must often be controlled, because when they operate on their own, in open loop:

- They would be unstable
- Safety or economical limits for the signals would not be satisfied

This means that u(k) is computed using feedback from y(k): the system operates in closed loop

Closed-loop identification

However, most of the techniques that we studied assume the system functions in open loop! For instance, IV guarantees require (among other things):

• ...

• The input signal *u*(*k*) does not depend on the disturbance (the experiment is open-loop)

...

Removing this condition leads to **closed-loop identification**.

Several techniques can be modified for this setting, notably including prediction error methods.

Here, we will focus on IV methods since they are easy to modify.

Analytical development of IV methods

Matlab example

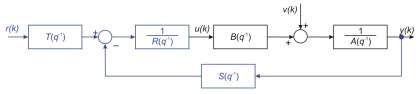

Theoretical guarantees

Closed-loop identification using IV

Closed-loop IV structure

$$\begin{aligned} &A(q^{-1})y(k) = B(q^{-1})u(k) + v(k) \\ &B(q^{-1})u(k) = T(q^{-1})r(k) - S(q^{-1})y(k) \end{aligned}$$

R, T, S polynomials

Therefore, in general u(k) depends:

- dynamically (via $R(q^{-1})$),
- on the system output with negative feedback through $S(q^{-1})$,
- and through $T(q^{-1})$ on an external input r(k)
 - usually a reference signal

The open-loop condition will of course fail. Let us dig deeper into it. The underlying reason for which we needed the loop open was to make the parameter errors:

$$\widehat{\theta} - \theta_0 = \left[\frac{1}{N}\sum_{k=1}^N Z(k)\varphi^\top(k)\right]^{-1} \left[\frac{1}{N}\sum_{k=1}^N Z(k)v(k)\right]$$

equal to zero, leading to a good model. For this, we require:

- $E \{Z(k)v(k)\}$ zero.
- $E \{Z(k)\varphi^{\top}(k)\}$ invertible.

With the usual IV choices, computed based on u (which now depends on y and hence on v), the first condition would fail.

Matlab example

Theoretical guarantees

Closed-loop identification using IV

Closed-loop IV idea

The vector of IVs Z(k) is not allowed to depend on u(k) anymore.

Idea: make it a function of r(k)!

Then:

- E {*Z*(*k*)*v*(*k*)} will naturally be zero, since we are the ones generating the reference *r*, independently from the disturbance *v*
- We can make E {Z(k)φ^T(k)} invertible by ensuring the IVs are good (e.g. no linear dependence), and that the reference *r* has a sufficiently high order of PE

Simplest idea – include in *Z* the appropriate number of delayed reference values:

$$Z(k) = [r(k-1), r(k-2), \dots r(k-na-nb)]^{\top}$$

Slightly generalized to linear combinations of these values:

$$Z(k) = \mathbf{F} \cdot [r(k-1), r(k-2), \dots r(k-na-nb)]^{\top}$$

where F is invertible. The simple case is recovered by taking F the identity matrix.

Analytical development of IV methods	Matlab example	Theoretical guarantees	Closed-loop identification using IV
Summary			

- Objective: combine simplicity of ARX linear regression with generality of PEM disturbance *v*
- Examined in-depth why ARX fails for colored disturbance v
- Solution: replace regressors φ (at strategic places in equations) by *instrumental variables Z* that do not depend on y
- Several ways to compute Z from u only
- Solution quality dependent on Z, may even be unstable
- Matlab example
- Further generalizing Z to depend only on reference r allows IV to work in closed-loop
